

Day 2(2): Research & list 3 popular CPU socket types (Ex: LGA1151, AM4, LGA1200) & name one compatible CPU model for each.

→ (1) Socket AM5 (AMD):

- Description: AMD's desktop platform introduced for DDR5 & PCIe 5.0 support,

- Compatible CPU: AMD Ryzen 7 7800X3D

(2) LGA1700 (Intel):

→ • Description: Intel's platform used for 12th, 13th & 14th Generation Intel core processors.

- compatible CPU: Intel core i5-13600K

(3) Socket AM4 (AMD):

→ • Description: One of the longest-lasting desktop platform from AMD, supporting Ryzen 1000 through 5000 series processors.

Day 2(3) Explain in your own words the primary function of CPU & the chipset on a motherboard, & describe how they work together when you open a music app like Spotify.

→ The CPU:

actual

The CPU does all the decision-making. It runs the app's code, calculates what needs to happen next,

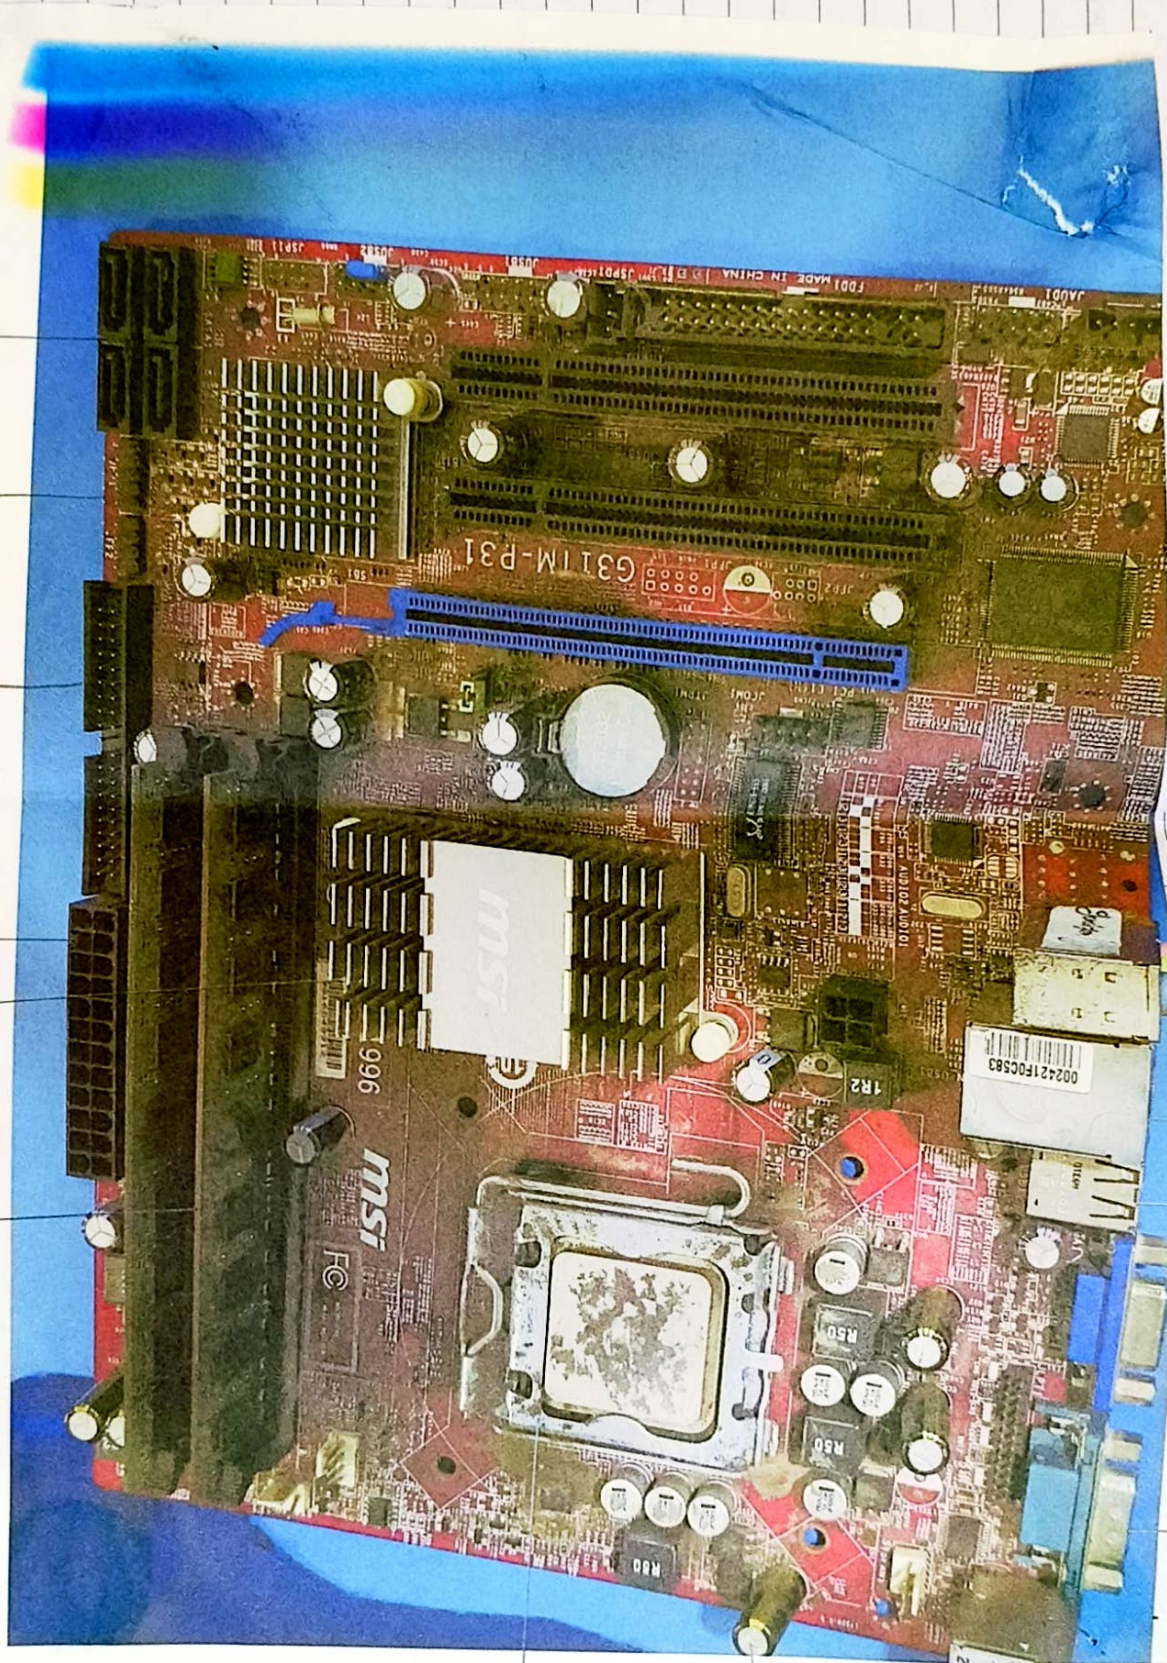

It tells every other components what to do.

The chipset:

The chipset is the network of roads on the motherboard. It connects the CPU to all your extra hardware like your mouse, keyboard, hard drive, WI-FI card, & speakers for making sure signals travel smoothly between them.

How They work Together to open Spotify:

- (1) You click: When you ^{double} click Spotify icon, your mouse sends signal to the chipset. The chipset immediately passes this message to the CPU.
- (2) Fetching the data: The CPU says, "lets open Spotify" it tells the chipset to retrieve Spotify's files from your storage drive (SSD) & load them into memory.
- (3) connecting online: As Spotify opens, the CPU uses the chipset to talk to your WI-FI or Internet card so it can load your playlist & song list.
- (4) Playing music: The CPU processes the music file & sends the ~~see~~ sound data through the chipset straight to your speakers or headphones so you can listen.
